- The Graph Cut Technique
- Patch Placement
- Image Synthesis Results
- Video Synthesis
- Conclusion

# The Goal of Texture Synthesis

Given a finite sample of some texture, the goal is to synthesize other samples from that same texture

# The Challenge

- Need to model the whole spectrum: from repeated to stochastic texture

**repeated**

**stochastic**

**Both?**

# Related work

Texture synthesis techniques that generate an output texture from an example input can be roughly categorized into three classes.

- A fixed number of parameters within a compact parametric model to describe a variety of texture
  - [Heeger and Bergen 95]
- Non-parametric, use a collection of exemplars to model the texture
  - [DeBonet 97], [Efros and Leung 99], [Wei and Levoy 00]
- Patch quilting
  - [Ashikmin 01], [Efros and Freeman 01]

# Heeger Bergen 1995

- Texture model:
  - Histograms of responses to various filters
- Avoiding copying:
  - Inherent in algorithm
- No user intervention required
- Captures stochastic textures well
- Does not capture structure
  - Lack of inter-scale constraints

# Results

## Successes

## Failures

# De Bonet 1997

- Texture model:
  - Feature vector containing multiscale responses to various filters
- Avoiding copying:
  - Random choice of pixels with 'close' feature vectors, but copying still frequent on small scale
- Individual per-filter thresholds are cumbersome
- Feature vectors used in later synthesis work

# Results

# Efros Leung 1999

- Texture model:
  - MRF
- Avoiding copying:
  - MRF
- Neighborhood size = largest feature size
- Search is very slow with large neighborhoods

# Results

# Ashikhmin 2001

- Texture model:
  - MRF
- Avoiding copying:
  - Actually, here it is encouraged on a small scale, but in practice it doesn't occur on a large scale
- Recognized that copying preserves fine detail

# Results

# Efros Freeman 2001

- Texture model:
  - ??
- Avoiding copying:
  - Randomized patch selection, but still noticeable
- Patch size is a hard parameter to understand

block

Input texture

Random placement  
of blocks

Neighboring blocks  
constrained by overlap

Minimal error  
boundary cut

# Minimal error boundary

overlapping blocks

vertical boundary

A diagram illustrating the calculation of overlap error. It shows two vertical blocks of the cell image, each with a thin vertical black line in its center. These blocks are enclosed in large square brackets. To the right of the brackets is a minus sign, followed by an equals sign, and then a vertical strip of the image. This strip shows the overlapping region of the two blocks, with a red line tracing the boundary between the two original blocks. A large number '2' is positioned to the right of the minus sign, indicating that the error is squared.

overlap error

min. error boundary

# Results

# Graph Basics

A graph is defined as

$$G = \{V, E\} \rightarrow V = \{s, t\} \cup P \rightarrow w(p, q) \square (p, q) \square E$$

V..... Set of nodes

E..... Set of links

P..... Set of non-terminal nodes  $V \setminus \{s, t\}$

s, t..... Terminal nodes

$w(p, q)$ .. Weight of the link (p,q)

note: the reverse weight (q,p) might have an other value

# Graph-Cuts

A s/t cut on a graph is a partition of the node-set  $V$  in two disjoint subsets, writing:  $C = \{S, T\}$

The cost of a cut is defined as:

$$|C| = \sum w(p,q), (p,q) \in E, p \in S, q \in T$$

That is, the sum over all “boundary links” of the cut.

The Minimum-Cut is the cut with the lowest cost of all possible cuts.

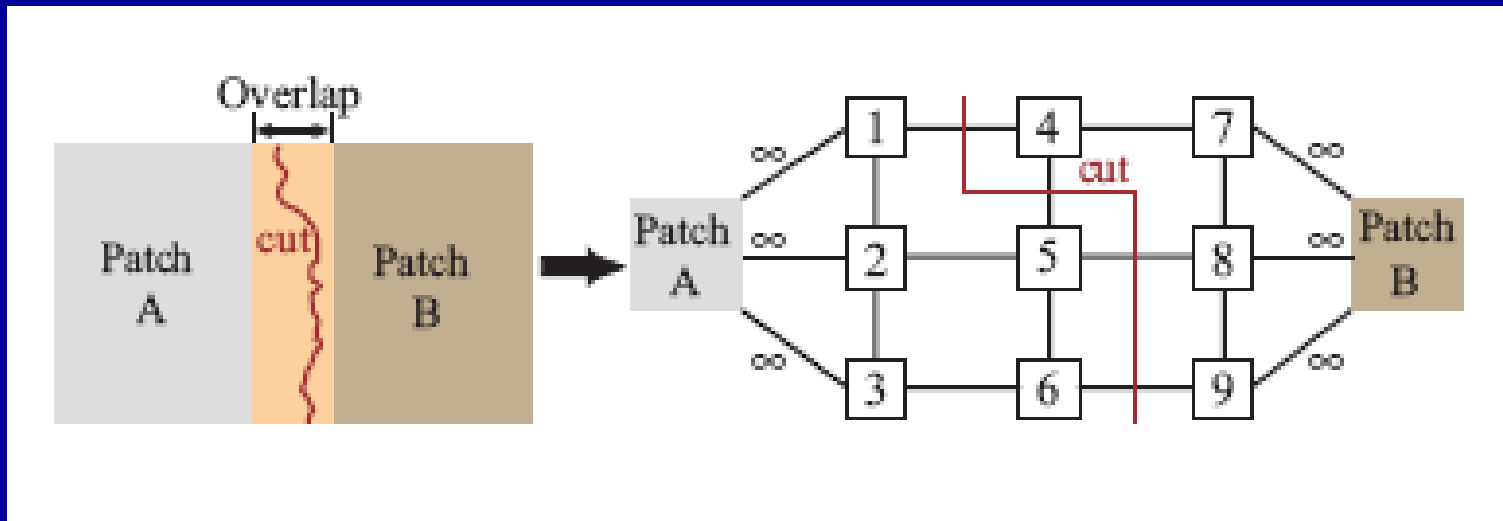

# Patch Fitting and Seam Computation

- Recovering the visually optimal seam by computing the minimum cut in the constructed graph:

Labels in this problem indicate whether a pixel in the output texture patch needs to come from the old patch or the new texture patch. The boundary of the new patch with the old texture is the new seam that is computed.

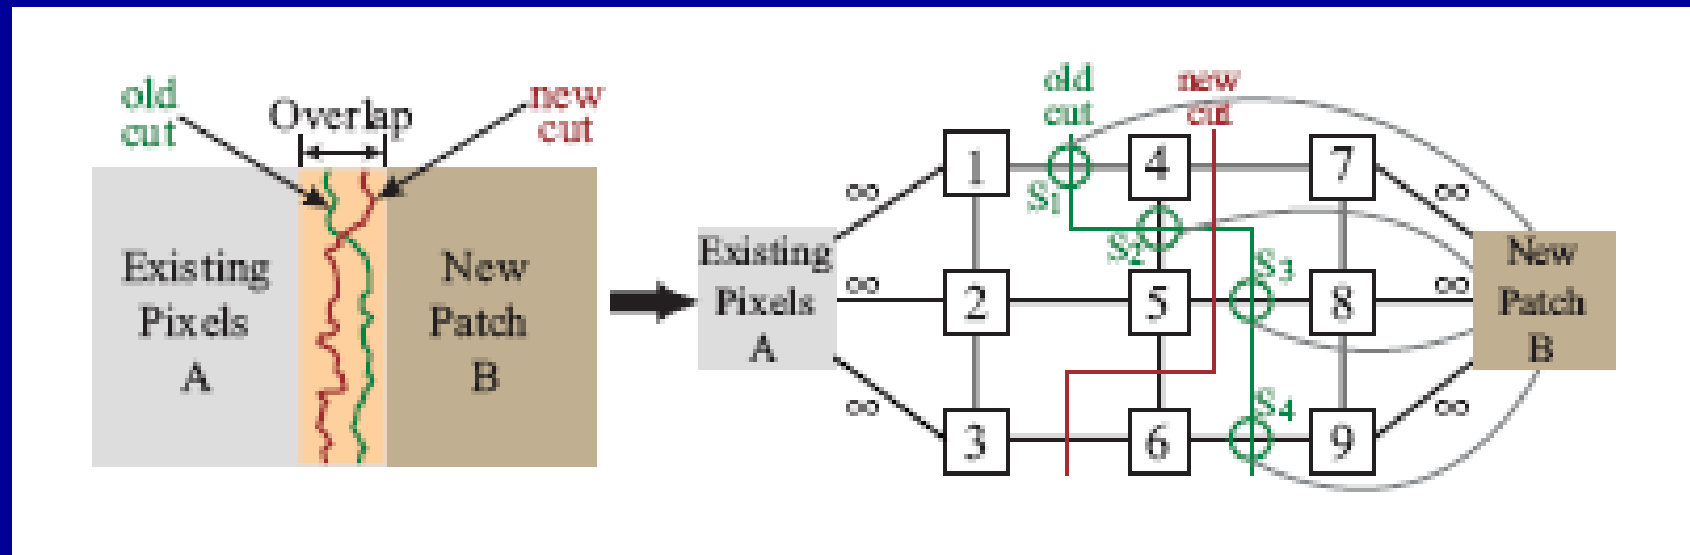

# A new way to find the cut

- Model overlapping patches as directed graphs
- Assign sources and sinks, and set the edges of adjacent pixel equal color difference
- $M(1, 4, A, B) = ||A(1) - B(1)|| + ||A(4) - B(4)||$
- run the min cut algorithm to find optimal seam

# Accounting for Old Seams

- We can incorporate old seam costs into the problem, and thus determine which pixels (if any) from the new patch should cover over some of the old seams.

# Surrounded Regions

- Sometimes we may want to cover old seams

# Patch Placement

- We've talked about how to fit the patch, but how do we lay down the texture patches?
  - Random Placement: Fast and works well for random textures
  - Entire Patch Matching: Normalize the sum-of-squared-differences and divide by area of patch. Pick a random, but good match.
  - Sub-Patch Matching: Pick a place in the output texture to place a patch, then search the input texture for the best match

# Results

# Extensions and Refinements

- **Adapting the Cost Function:** Pay attention to frequency content present in the image or video
- **Feathering and multi-resolution splining:** Reduces ability to notice obvious seams
- **FFT-Based Acceleration:** For patch matching. SSD can be expensive. One example had a reduction of 10 minutes to 5 seconds after switching to the FFT method.

# Additional Transformations

- Input image can be rotated, mirrored and scaled to produce interesting results

# Additional Transformations Continued

# Rotation Example

- Image Quilting vs Graph Cut

Input

Graph Cut Result

Image Quilting Result

# Interactive Graph Cuts

- User has a hand in placing image, graph cut algorithm then finds the best cut

# Interactive Graph Cuts Continued

# Video Synthesis

- Video textures turn existing video into an infinitely playing form by finding smooth transitions from one part of the video to another
- Patches in the case of video are the whole 3D space-time blocks of video

# Video Synthesis Continued

# Conclusion

- A new texture synthesis algorithm was introduced that works not only in 2D, but in 3D
- It's has advantages over previous patch based methods
- It's very fast, taking between 5 seconds and 5 minutes to generate results

# Results of Video Synthesis
